# PROJECT CONTEXT & OBJECTIVES

## Project: Inventory Management System

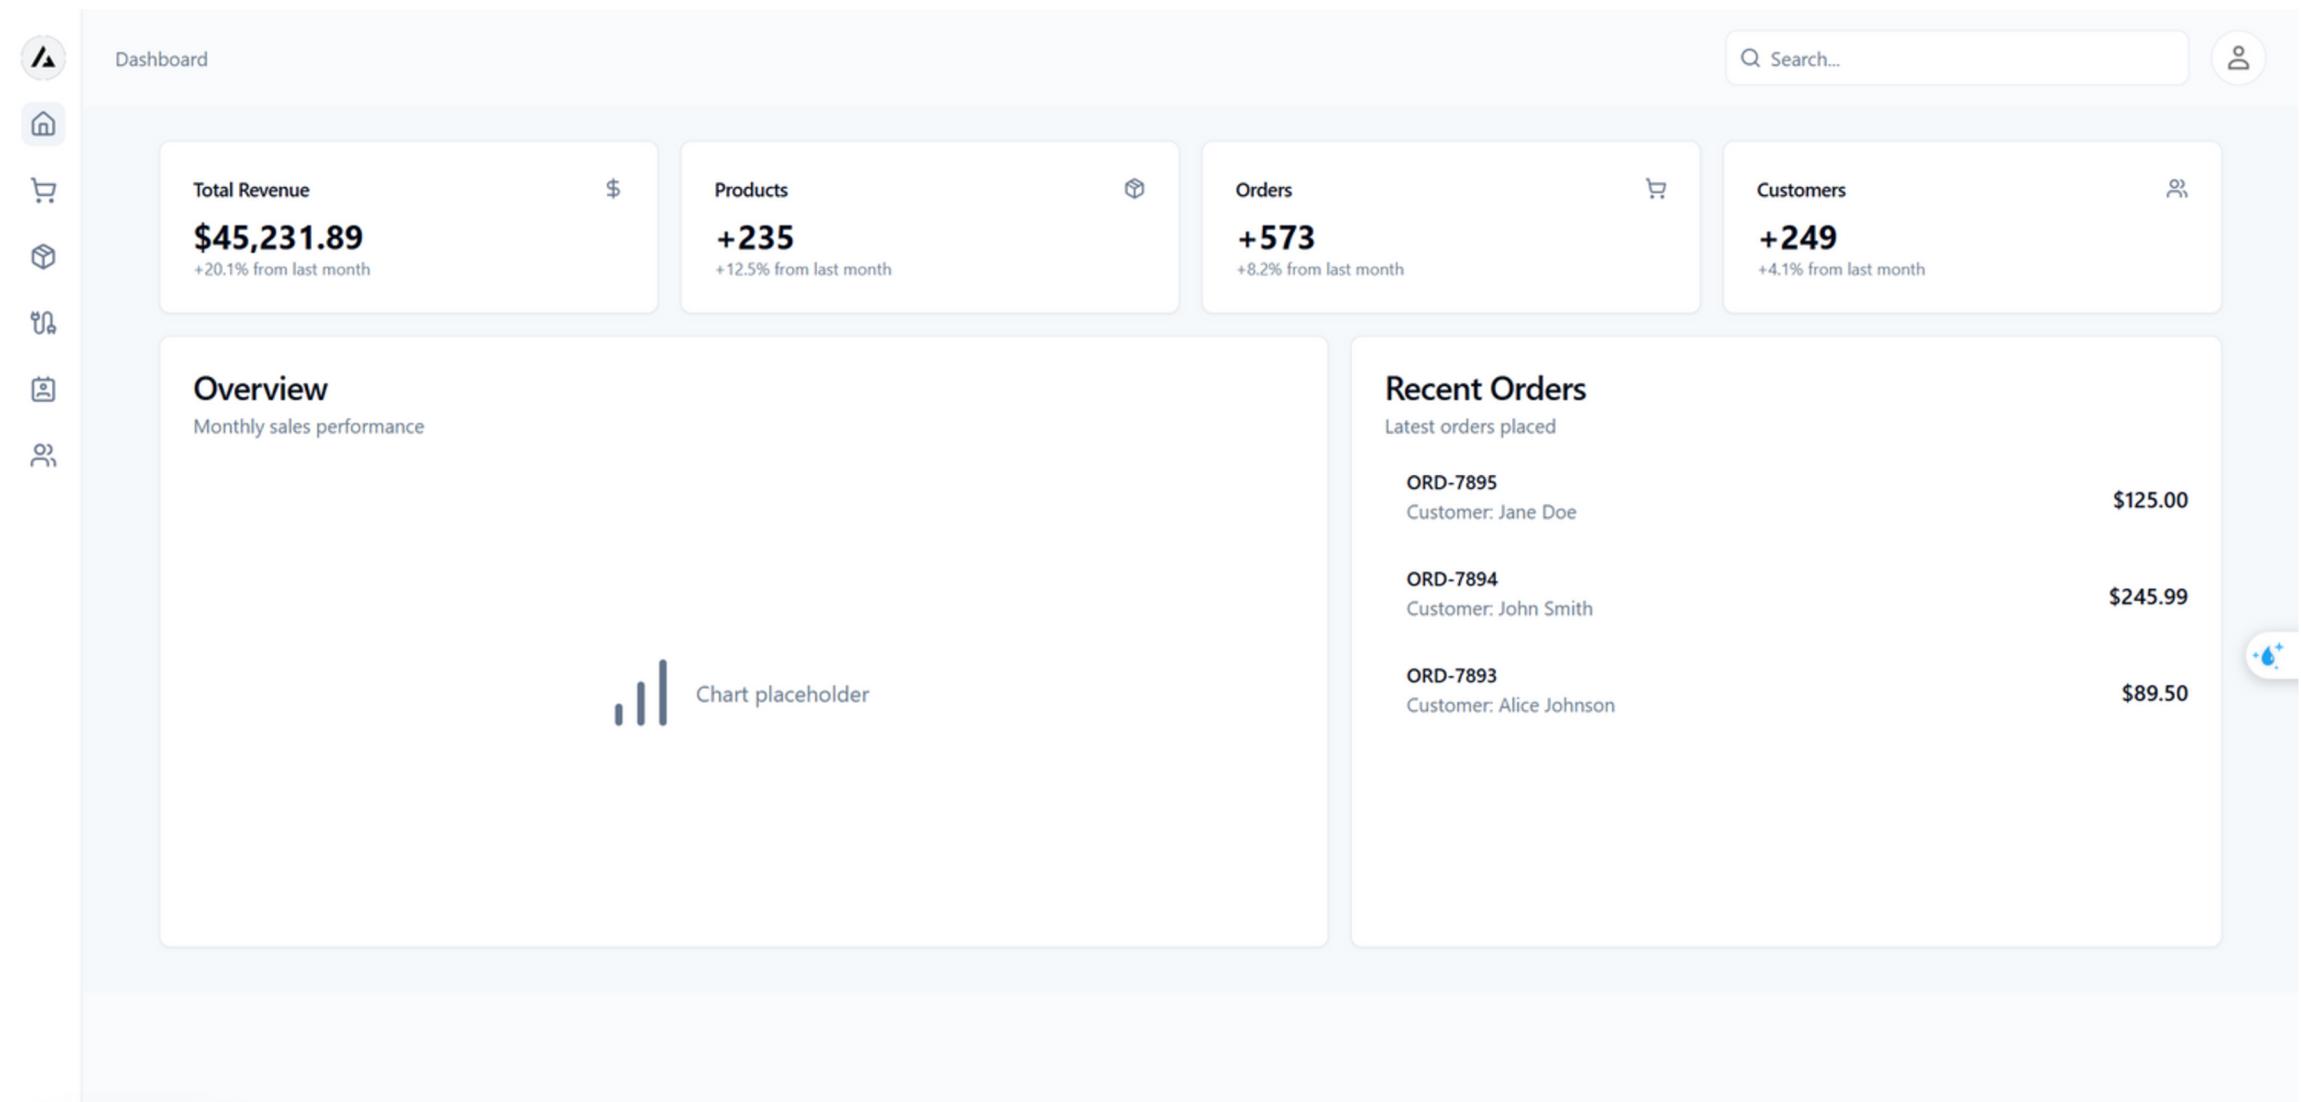

- Manages: Products, orders, users, and related entities.

### Primary Goal:

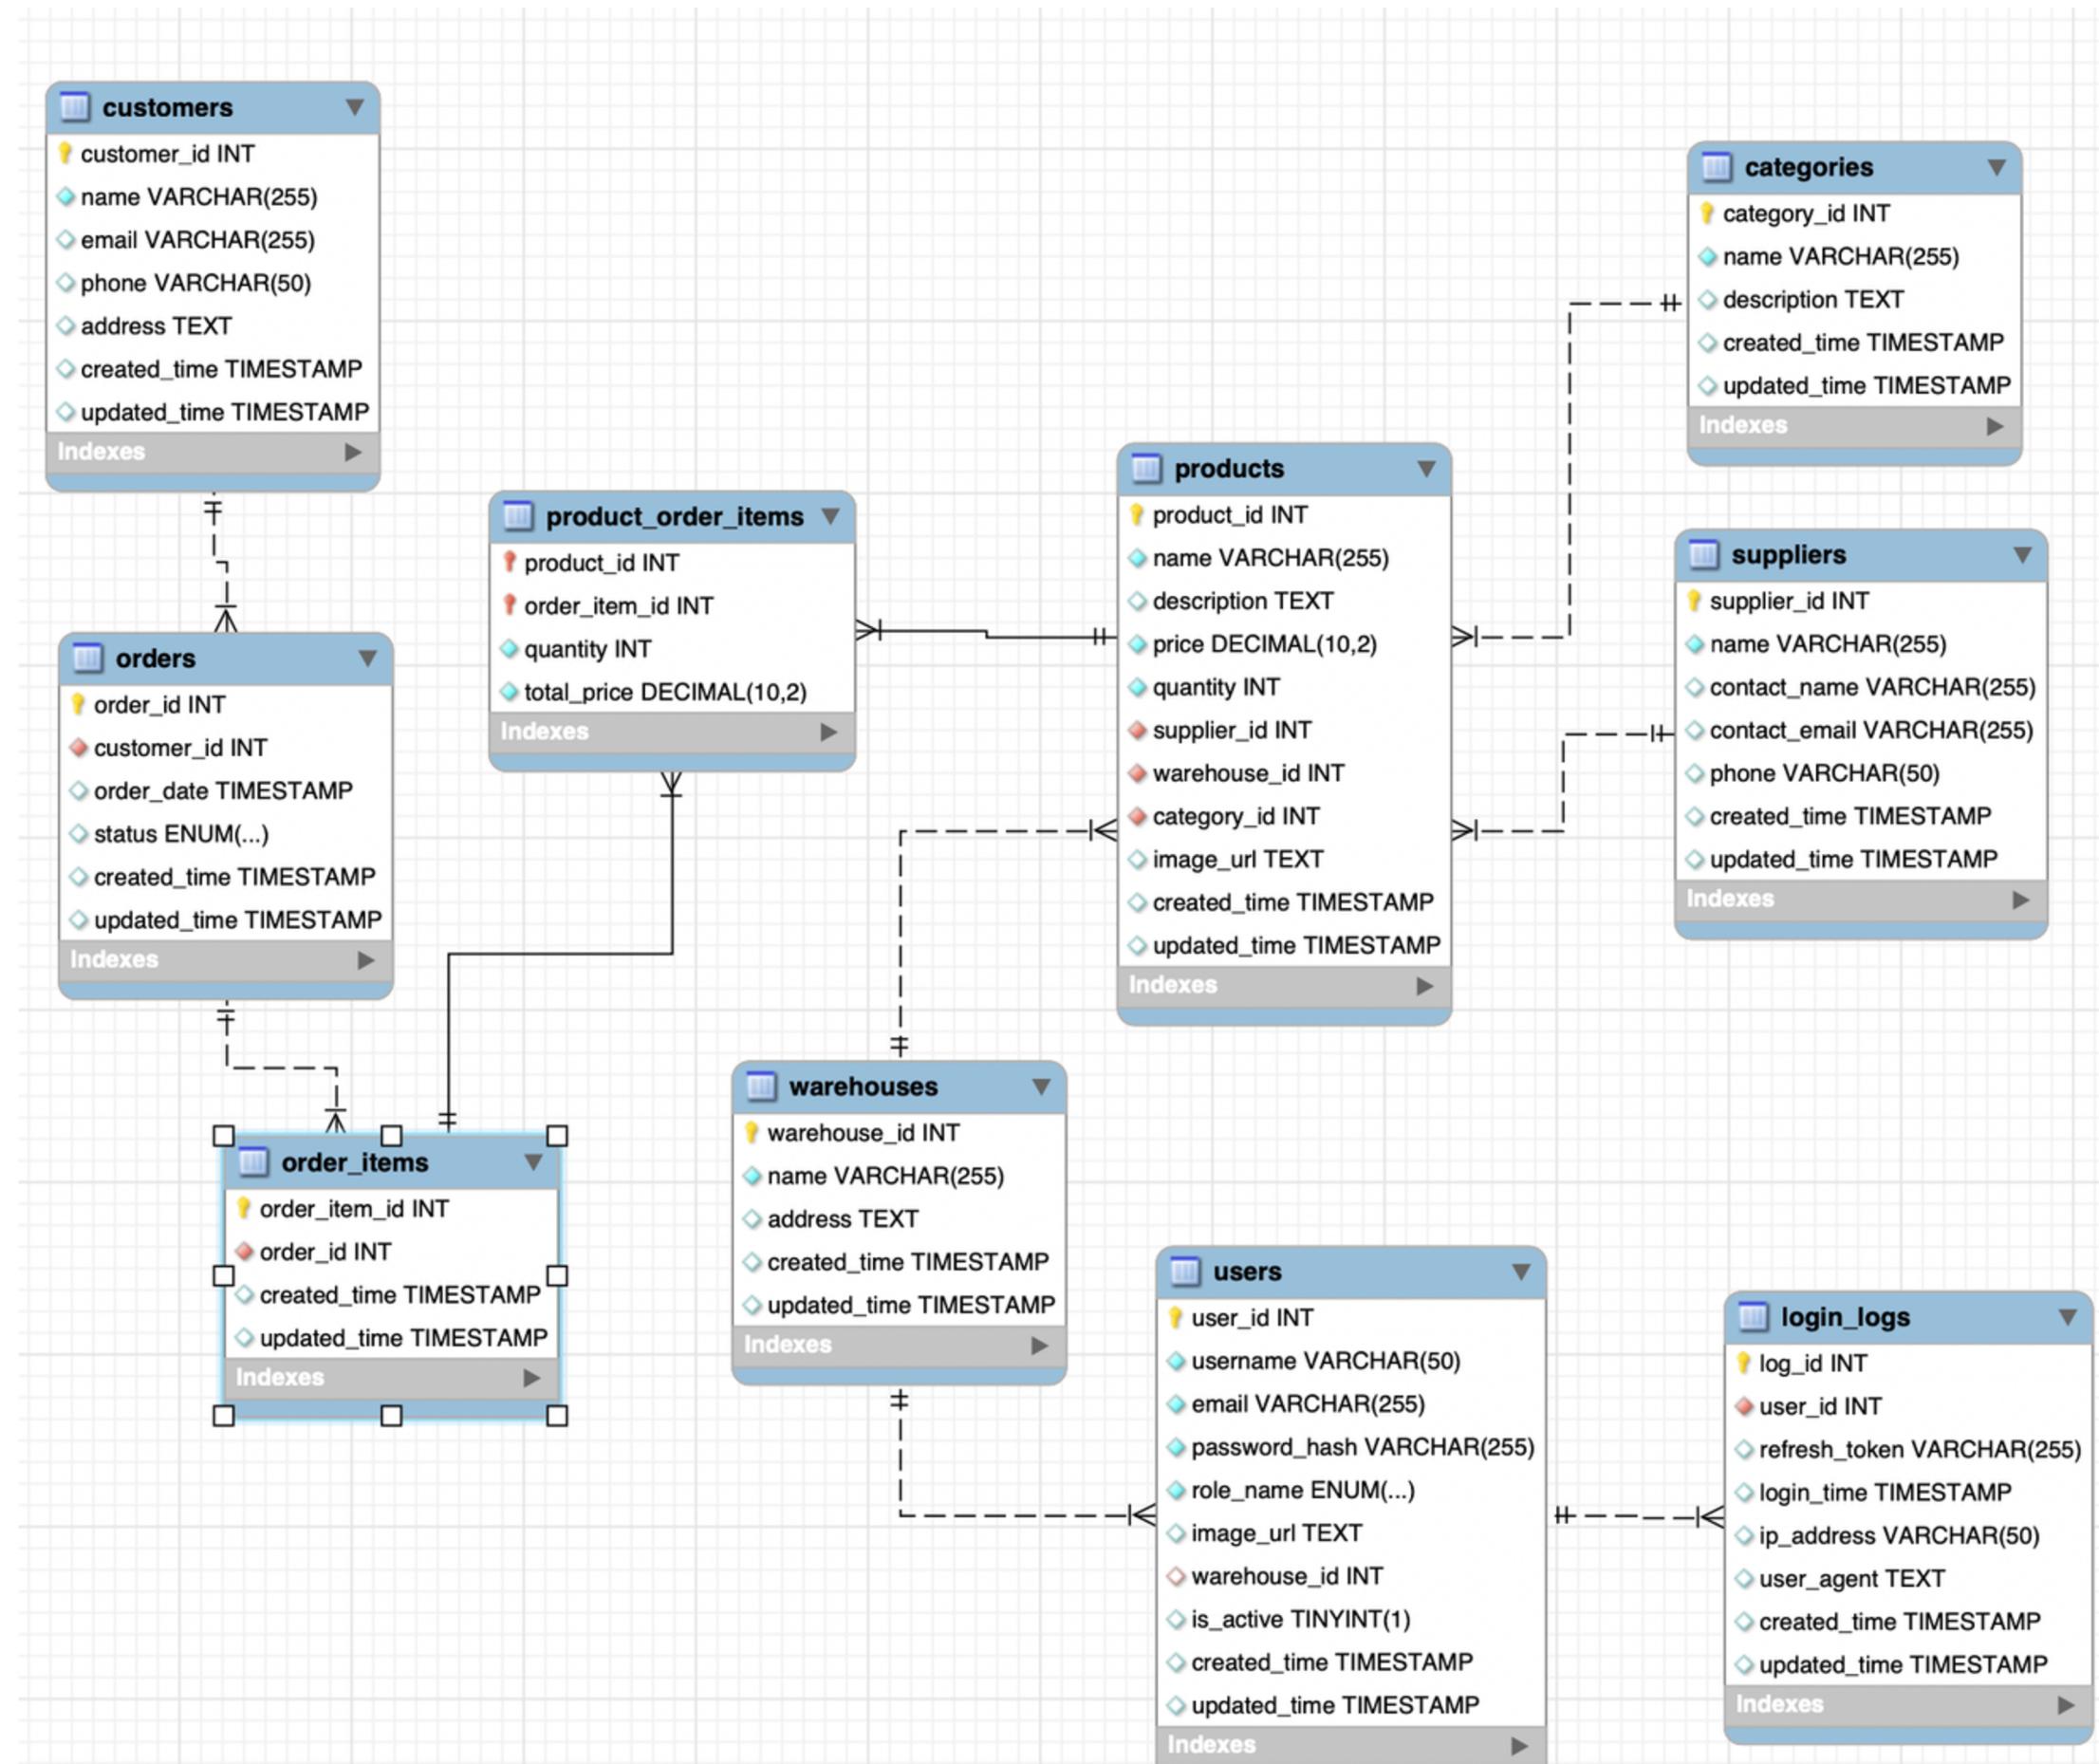

- Demonstrate a fully functional, performant, and secure system meeting all project requirements.

### Core Technologies:

- MySQL (Database)
- Next.js (Web Interface)
- Redis (Caching)
- Docker (Deployment)]

# SCHEMA IMPLEMENTATION

# KEY PERFORMANCE OPTIMIZATIONS

## Strategic Indexing:

- On Foreign Keys & frequent search columns (e.g., products.category\_id, products.name).

```
-- Indexes
-- Users Email Index
-- Rationale: Speeds up Login queries and email-based Lookups
CREATE INDEX idx_users_email ON users(email);

-- Products Name Index
-- Rationale: Accelerates product searches by name
CREATE INDEX idx_products_name ON products(name);

-- Orders Date Index
-- Rationale: Optimizes queries filtering orders by date
CREATE INDEX idx_orders_date ON orders(order_date);
```

# SECURITY CONFIGURATIONS

## Access Control & Authorization:

- Roles: Admin (full) & Staff (activated by admin, assigned to specific warehouse\_id for limited access).
- Token-Based: JWT & 64-char random string (Refresh Token).
- Middleware (login\_required): Validates Access Token (signature, expiration, role, warehouse, cache blacklist).
- Secure Logout: Deletes Refresh Token from login\_log, blacklists Access Token in cache (until 1hr expiry).

## Secure Password Storage:

- Bcrypt hashing (application-level) with automatic salting & configurable work factor.
- Explicitly not using weaker MySQL hash functions (MD5/SHA1) due to lack of salt & vulnerabilities.

## SQL Injection Prevention:

- Prepared statements with parameterized queries used for all database interactions.
- Separates SQL code from user data, preventing malicious input.
